Exam : **TA03**

Title : Blue Prism Technical Architect

Version : DEMO

1.A developer who has worked on several production automations is leaving the organisation. Their access is being removed as part of the standard leaver process.
Which step closes the exposure the departure creates?
A. Change any credential the developer could have read or handled during their work.
B. Reassign ownership of the automations and Objects they built, so that each one has a named maintainer.
C. Re-import the automations they built from their release files, so that no unreviewed change remains.
D. Review the session logs of the automations they built, to confirm nothing unexpected has run.
Answer: A

2.A regulated client needs separate areas for development, testing, release validation and production operations, with controlled promotion between them.
What should the architect define?
A. Separate environments for development, testing, pre-production and production, each with its own governance.
B. One shared environment, with naming conventions and folder structures distinguishing work in progress from work that is already live.
C. One shared environment in which developers test directly against production data, shortening the release cycle.
D. Runtime Resource pools used in place of environment separation, with a pool dedicated to each stage of the lifecycle.
Answer: A

3.A client plans to grow its digital workforce over the next two years and asks the architect what constrains how many Digital Workers can run concurrently.
Which answer is correct?
A. The number of Runtime Resources defined in the environment, since each definition permits one concurrent session.
B. The number of published Processes, because each published Process reserves capacity when it is made available.
C. The number of work queues configured, because each queue admits only a fixed number of sessions, and the total across the estate sets the ceiling.
D. The licensed concurrent-worker entitlement, alongside the infrastructure capacity provisioned to host and support them.
Answer: D

4.What ensures that credentials stored in Blue Prism can be retrieved only by the automations entitled to use them?
A. Encrypt and decrypt each credential inside the automation itself, so the value never sits in the clear
B. Restrict each credential so that only nominated roles, processes and resources are permitted to retrieve it
C. Grant every Runtime Resource access to all credentials, so that automations never fail on a permission error
D. Reliance on database encryption at rest, which prevents unauthorised automations from retrieving

credentials
Answer: B

5.Delivery teams have begun downloading reusable assets published for the platform and importing them into the development environment as they find them.
What should the architect put in place?
A. A rule that assets may be imported into development freely, reviewed later, and assessed only when a release reaches production.
B. A requirement that every downloaded asset be rebuilt in house before use, so nothing external enters the estate.
C. A review before import, so that each asset is assessed and a known version is recorded.
D. A restriction limiting imports to the architect's own account, so that all imports pass through one person.
Answer: C
